Teach me about regression testing in software development as i am very beginner in software domain.First explain what it is and then after approval step2,step3..

Regression testing means re-running existing tests after a software change to make sure that features which used to work still work. It catches unintended "side effects" from bug fixes, new features, or code updates. [1] [2]

Simple example

Imagine an online shopping app:

- Users can log in, search products, add items to the cart, and pay.
- A developer changes the **cart** page to add a discount feature.
- Later, testers discover that the **payment** button no longer works.

That is a *regression*: the new change accidentally broke something that previously worked. Regression testing would have re-checked login, cart, checkout, and payment after the cart change to catch this early. [3] [4]

Why it matters

Software is interconnected: changing one part can affect another. Regression testing acts as a safety net, especially before releases, after bug fixes, and after updates to libraries or infrastructure. [1] [3]

Term	Meaning
Regression	A previously working feature becomes broken.
Test case	A specific check, such as "user can log in with valid credentials."
Regression suite	A collection of important repeatable tests.
Automation	Software runs the tests automatically, usually through CI/CD pipelines. [2] [3]

Step 2 preview

Once you approve, I'll explain **Step 2: How regression testing works**, including:

- What a test case is
- What a regression test suite is
- When teams run regression tests
- Manual testing versus automated testing

Shall I continue with **Step 2**?
